

# Map

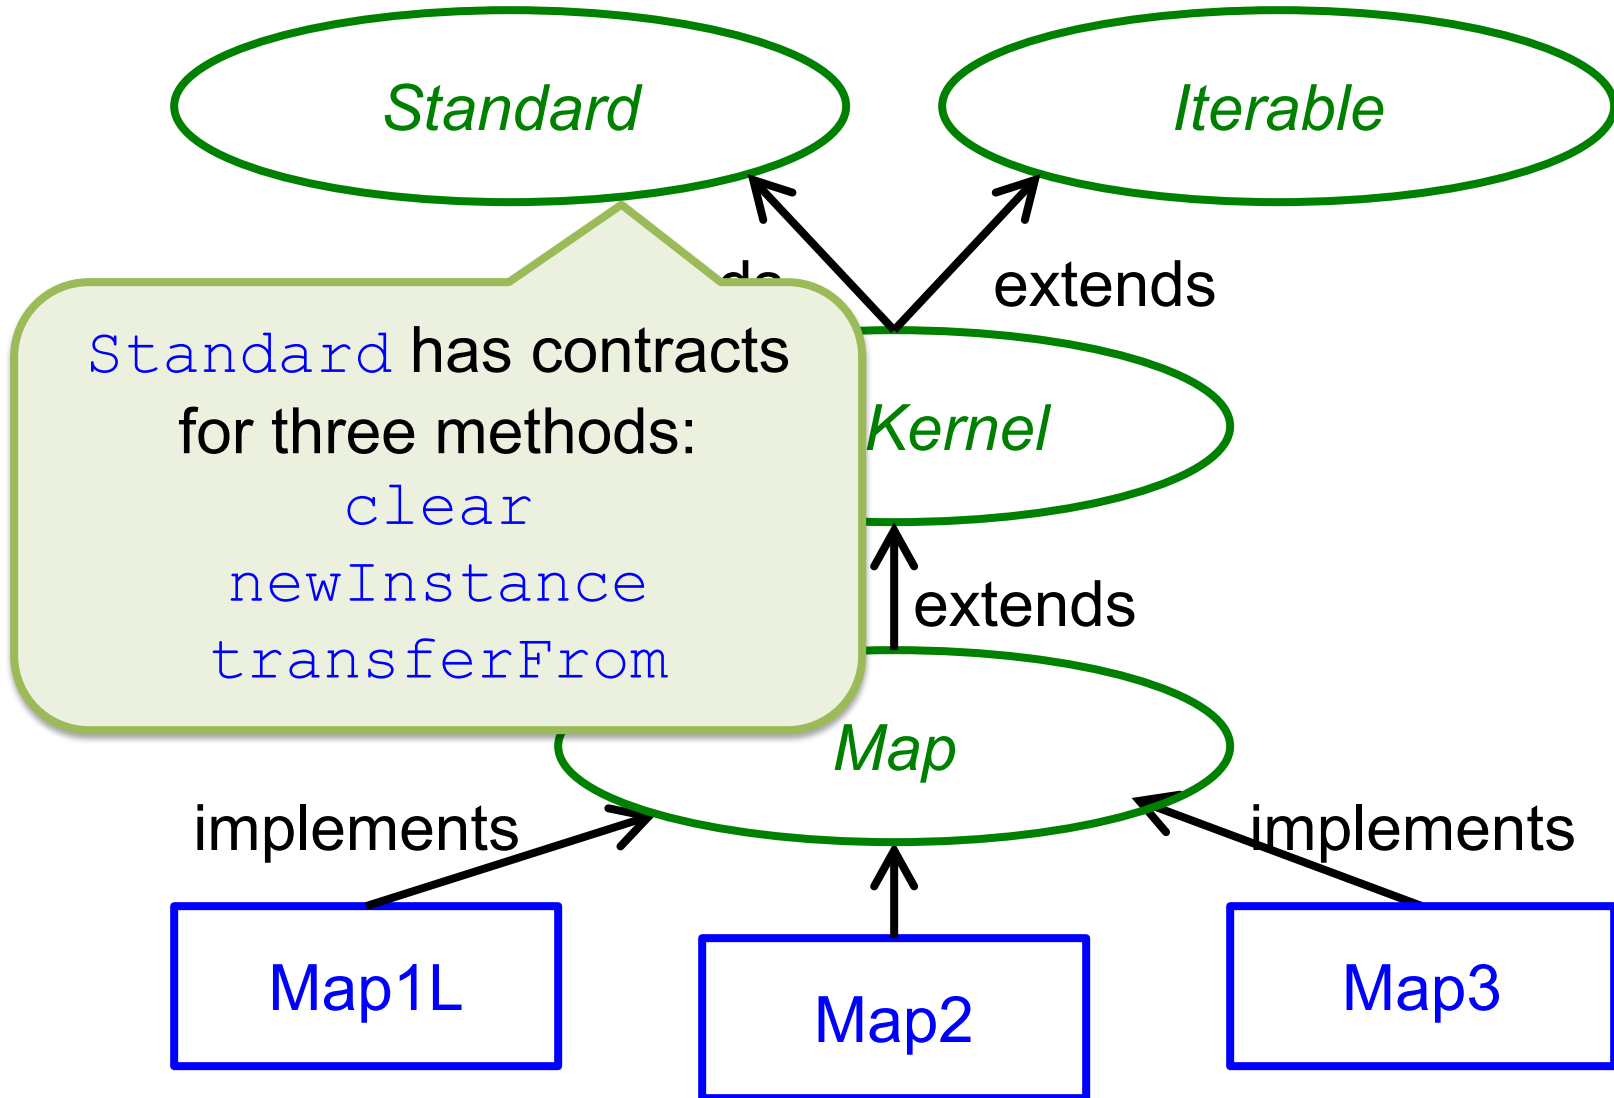

# Map

- The **Map** component family allows you to manipulate **mappings** from **keys** (of any type `K`) to **values** (of any type `V`)
  - A `Map` variable holds a very simple “database” of keys and their associated values
  - Example: If you need to keep track of the exam grade for each student, you might use a `Map<String, Integer>` variable

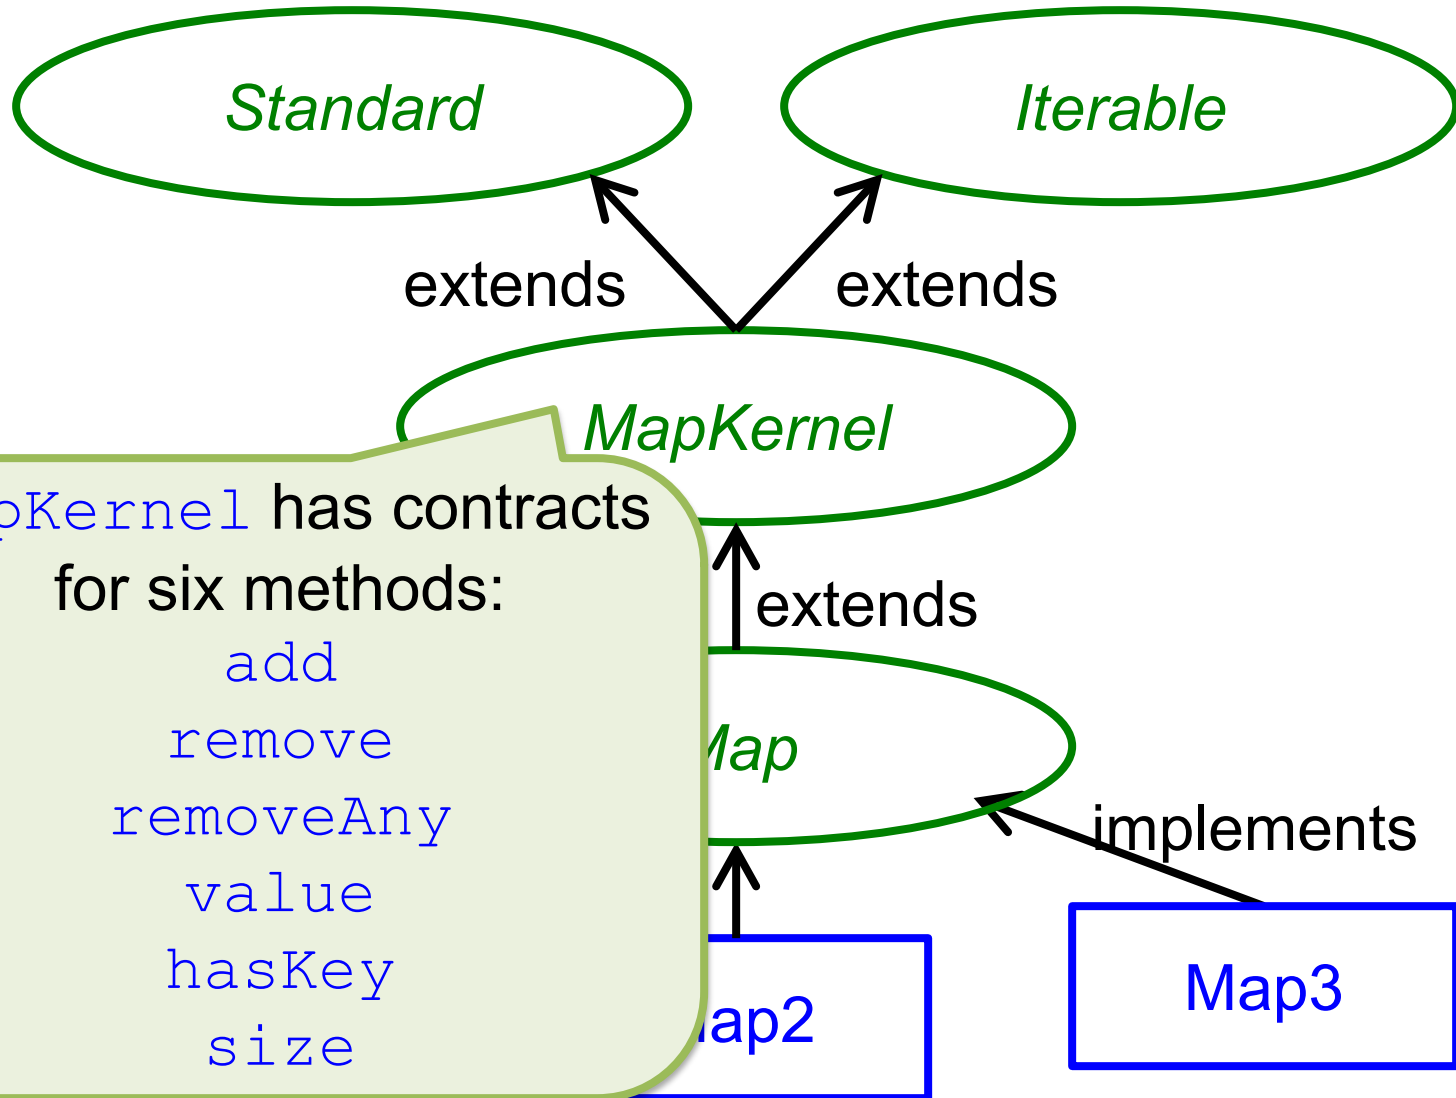

# Interfaces and Classes

# Interfaces and Classes

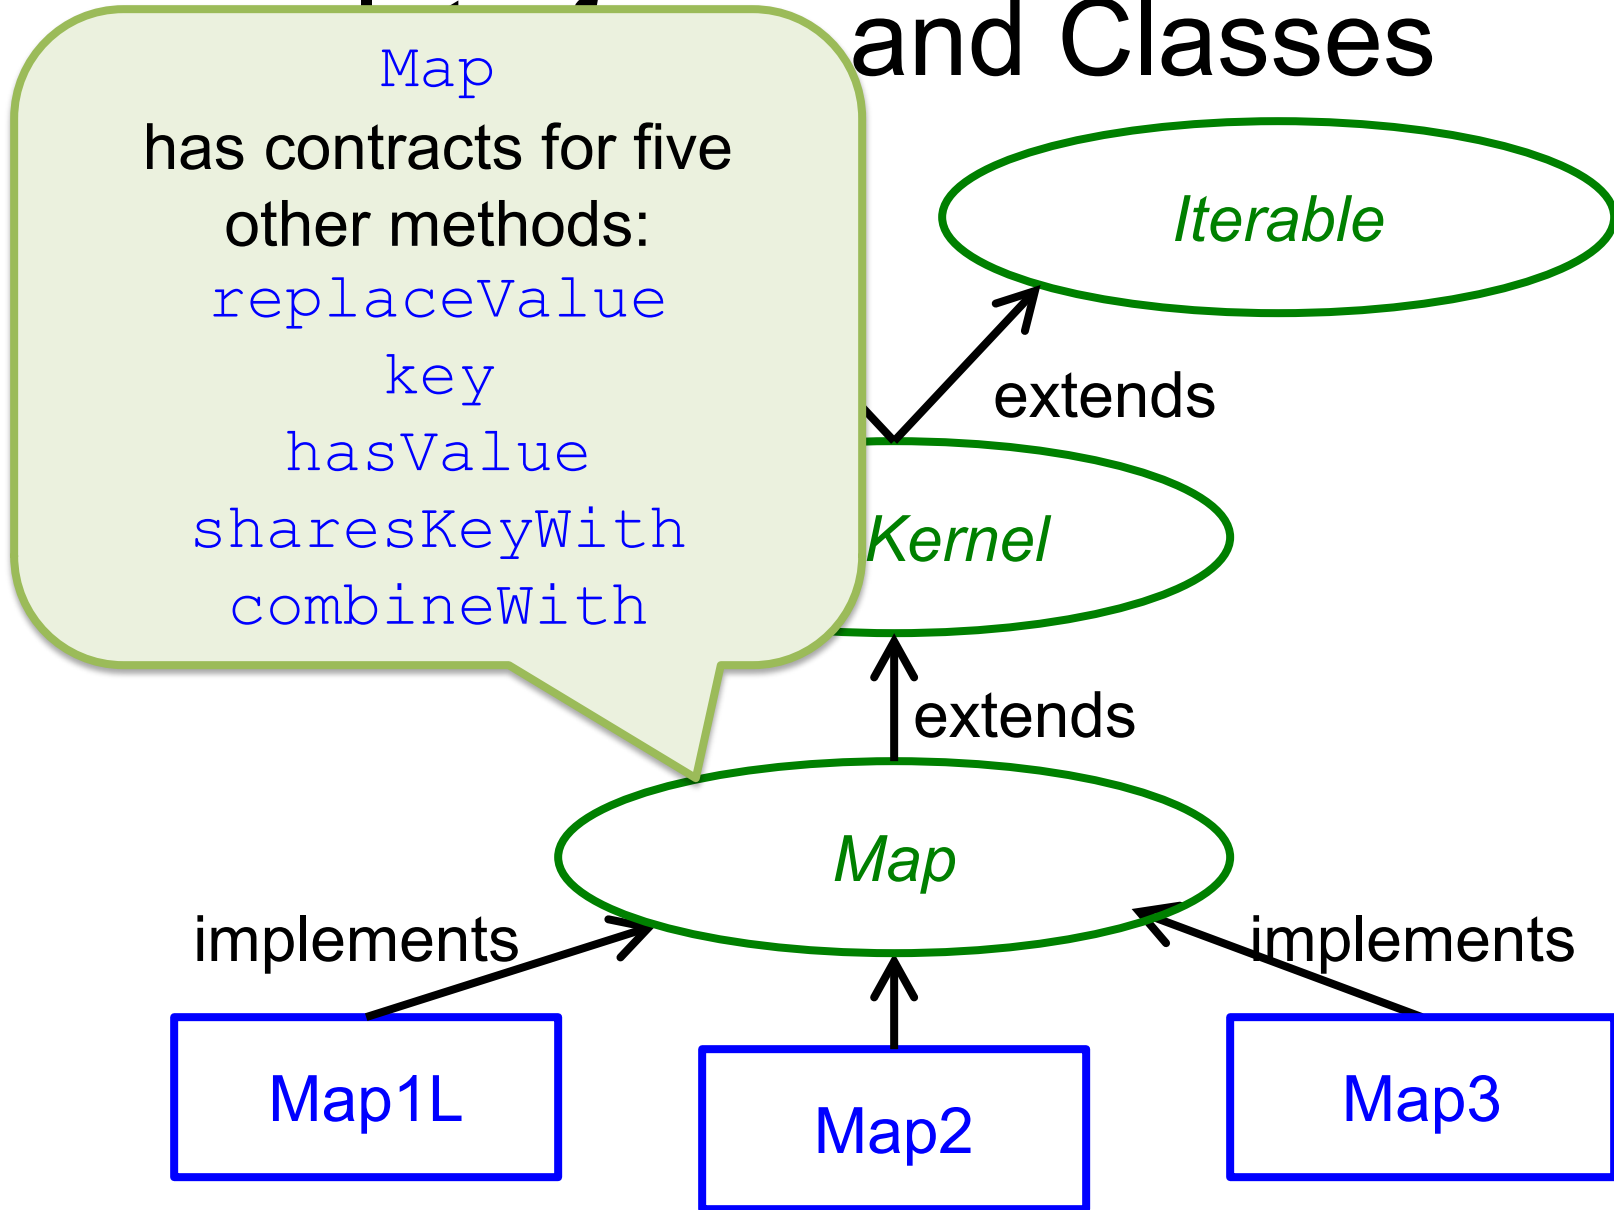

# Interfaces and Classes

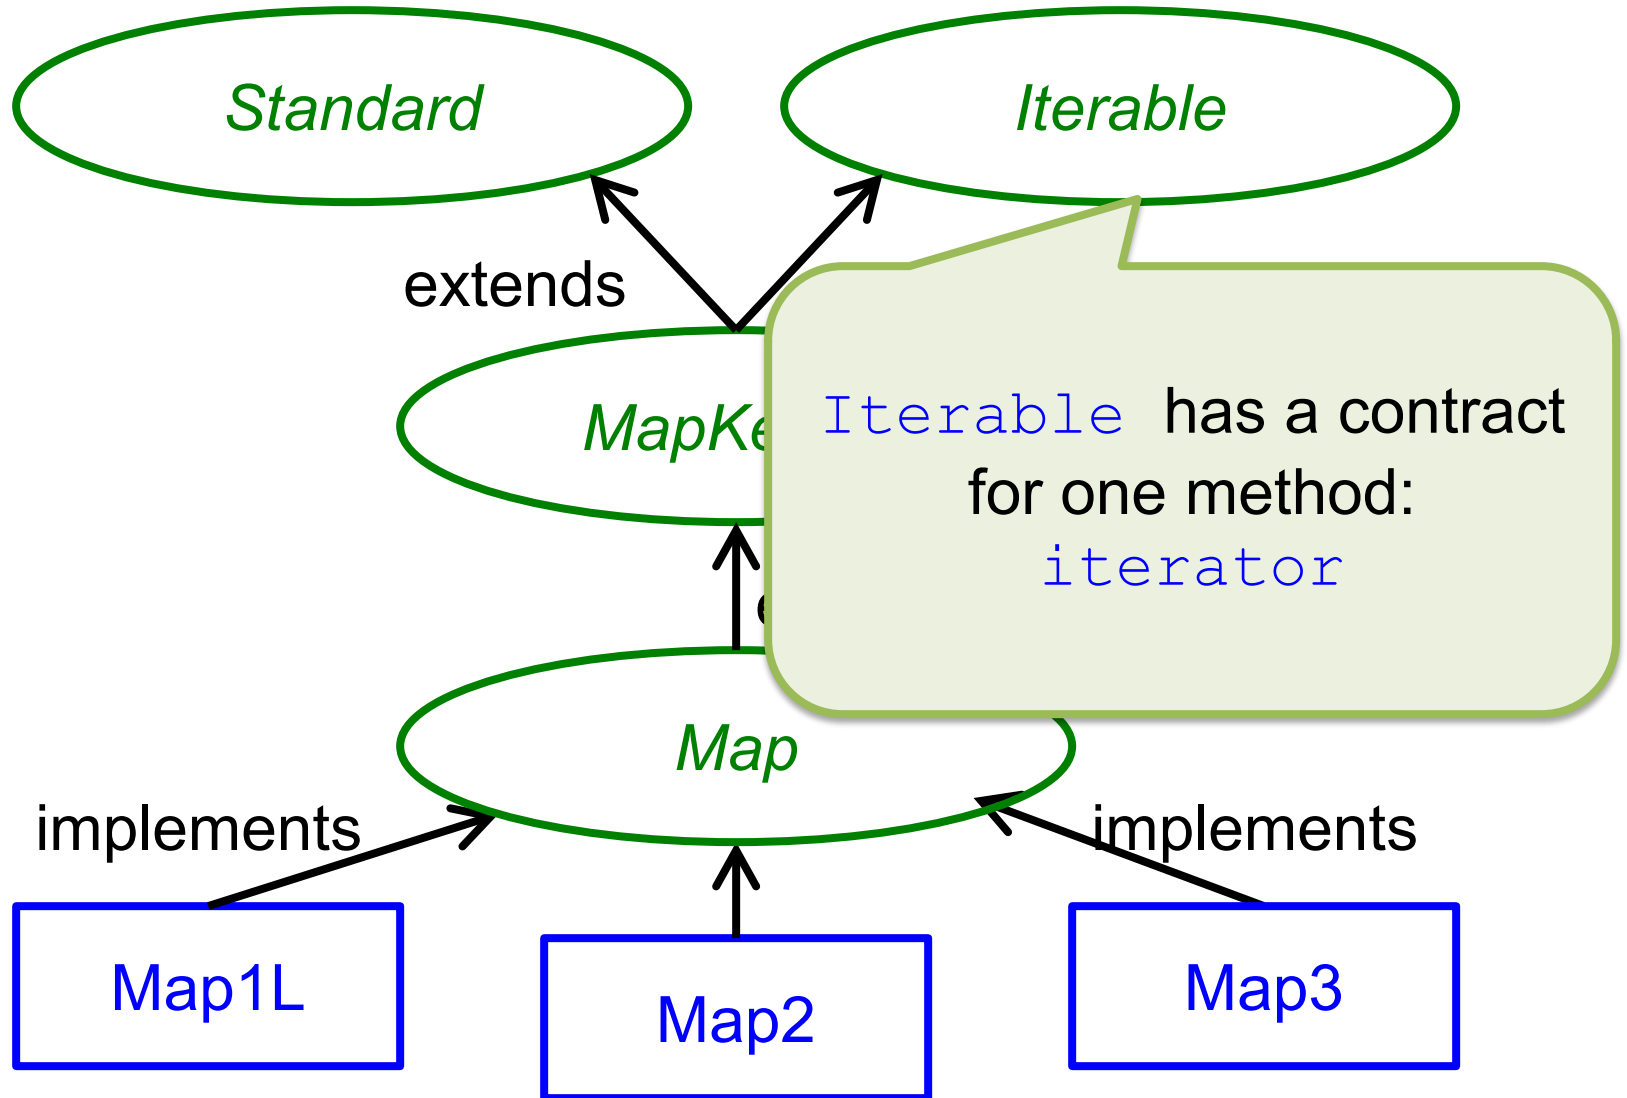

*MapKernel* has contracts for six methods:  
add  
remove  
removeAny  
value  
hasKey  
size

# and Classes

# Interfaces and Classes

# Mathematical Model

- The value of a `Map` variable is modeled as a finite set of ordered pairs of type  $(K, V)$  with “the function property”, i.e., no two pairs in the set have the same `K` value
  - This is sometimes called a (finite) ***partial function from `K` to `V`***

# Partial Function

*PARTIAL\_FUNCTION is finite set of*

*(key: K, value: V)*

***exemplar*** *m*

***constraint***

***for all*** *key1, key2: K, value1, value2: V*

***where*** *((key1, value1) is in m and*

*(key2, value2) is in m)*

***(if*** *key1 = key2 then value1 = value2)*

# Partial Function

*PARTIAL\_FUNCTION* **i**  
*(key: K, value*  
**exemplar** *m*  
**constraint**

This formally states “the function property” for a set of ordered pairs.

**for all** *key1, key2: K, value1, value2: V*  
**where** *((key1, value1) is in m and*  
*(key2, value2) is in m)*  
**(if** *key1 = key2 then value1 = value2)*

# Domain of a (Partial) Function

```
DOMAIN (  
    m: PARTIAL_FUNCTION  
): finite set of K  
satisfies  
    for all key: K  
        (key is in DOMAIN(m) iff  
            there exists value: V  
                ((key, value) is in m))
```

# Range of a (Partial) Function

```
RANGE (  
  m: PARTIAL_FUNCTION  
) : finite set of V  
satisfies  
  for all value: V  
    (value is in RANGE(m) iff  
      there exists key: K  
        ((key, value) is in m))
```

# Mathematical Model

- Formally:

*type Map is modeled by*

*PARTIAL\_FUNCTION*

# No-argument Constructor

- Ensures:

```
this = { }
```

# Example

<b>Code</b>	<b>State</b>
<pre>Map&lt;String,Integer&gt; m =   <b>new</b> Map1L&lt;&gt;();</pre>	

# Example

<b>Code</b>	<b>State</b>
<pre>Map&lt;String,Integer&gt; m =   new Map1L&lt;&gt;();</pre>	
	<pre>m = { }</pre>

# add

**void** add(K key, V value)

- Adds the pair (key, value) to **this**.
- Aliases: references key, value
- Updates: **this**
- Requires:

*key is not in DOMAIN(this)*

- Ensures:

*this = #this union { (key, value) }*

# Example

<b>Code</b>	<b>State</b>
	<pre>m = { ("PB", 99),       ("BW", 17) } k = "PS" v = 99</pre>
<pre>m.add(k, v);</pre>	

# Example

Is the requires clause satisfied? What is  $DOMAIN(m)$ ?

	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PS"$ $v = 99$
<code>m.add(k, v);</code>	

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PS"$ $v = 99$
<code>m.add(k, v);</code>	
	$m = \{ ("PB", 99), ("BW", 17), ("PS", 99) \}$ $k = "PS"$ $v = 99$

# Example

Note the aliases created here, which you cannot see in the tracing table; you should be able to draw the appropriate diagram showing them.

	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PS"$ $v = 99$
	$m = \{ ("PB", 99), ("BW", 17), ("PS", 99) \}$ $k = "PS"$ $v = 99$

# Another Interface

- The `Map` interface includes an interface for another related generic type, `Map.Pair`
- Its mathematical model is simply an ordered pair of a key and a value
- Formally:

***type** `Map.Pair` **is modeled by**  
`(key: K, value: V)`*

# Map.Pair Methods

- This (immutable) type has only a constructor (taking a `K` and a `V`) and a **getter** method for each pair component
  - `K key()`
    - Returns the first component of **this**
    - Aliases: reference returned by `key`
  - `V value()`
    - Returns the second component of **this**
    - Aliases: reference returned by `value`

# remove

`Map.Pair<K, V> remove (K key)`

- Removes from **this** the pair whose first component is `key` and returns it.

- Updates: **this**

- Requires:

*key is in DOMAIN(this)*

- Ensures:

*remove.key = key and*

*remove is in #this and*

*this = #this \ {remove}*

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "BW"$
<pre>Map.Pair&lt;String,Integer&gt; p =   m.remove(k);</pre>	

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "BW"$
<pre>Map.Pair&lt;String,Integer&gt; p = m.remove(k);</pre>	
	$m = \{ ("PB", 99) \}$ $k = "BW"$ $p = ("BW", 17)$

# removeAny

`Map.Pair<K, V> removeAny()`

- Removes and returns an arbitrary pair from **this**.

- Updates: **this**

- Requires:

***| this | > 0***

- Ensures:

***removeAny is in #this and***

***this = #this \ {removeAny}***

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17), ("PS", 99) \}$
<pre>Map.Pair&lt;String,Integer&gt; p =   m.removeAny();</pre>	

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17), ("PS", 99) \}$
<code>Map.Pair&lt;String,Integer&gt; p = m.removeAny();</code>	
	$m = \{ ("PB", 99), ("BW", 17) \}$ $p = ("PS", 99)$

# value

V value (K key)

- Reports the value associated with `key` in **this**.
- Aliases: reference returned by `value`
- Requires:  
*key is in DOMAIN(this)*
- Ensures:  
*(key, value) is in this*

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = -423$
<code>v = m.value(k);</code>	

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = -423$
<code>v = m.value(k);</code>	
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = 99$

# Example

Note the alias created here, which you cannot see in the tracing table; you should be able to draw the appropriate diagram showing it.

	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = -423$
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = 99$

# hasKey

**boolean** hasKey (K key)

- Reports whether there is a pair in **this** whose first component is *key*.
- Ensures:

*hasKey* =

*(key **is in** DOMAIN (**this**))*

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$
<b>boolean</b> b = m.hasKey(k);	

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$
<b>boolean</b> b = m.hasKey(k);	
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $b = \mathbf{true}$

# size

```
int size()
```

- Reports the size (cardinality) of **this**.
- Ensures:

```
size = | this |
```

# replaceValue

V replaceValue(K key, V value)

- Replaces the value associated with `key` in **this** by `value`, and returns the old value.

- Aliases: reference `value`

- Updates: **this**

- Requires:

*key is in DOMAIN(this)*

- Ensures:

*this = (#this \ {(key, replaceValue)})  
union {(key, value)} and  
(key, replaceValue) is in #this*

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = 85$
<pre>Integer oldV =     m.replaceValue(k, v);</pre>	

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = 85$
<pre>Integer oldV =     m.replaceValue(k, v);</pre>	
	$m = \{ ("PB", 85), ("BW", 17) \}$ $k = "PB"$ $v = 85$ $oldV = 99$

# Example

Note the alias created here, which you cannot see in the tracing table; you should be able to draw the appropriate diagram showing it.

	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = 85$
	$m = \{ ("PB", 85), ("BW", 17) \}$ $k = "PB"$ $v = 85$ $oldV = 99$

# Another Example

<b>Code</b>	<b>State</b>
	<pre>m = { ("PB", 99),       ("BW", 17) } k = "PB" v = 85</pre>
<pre>v = m.replaceValue(k, v);</pre>	

# Another Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $k = "PB"$ $v = 85$
<code>v = m.replaceValue(k, v);</code>	
	$m = \{ ("PB", 85), ("BW", 17) \}$ $k = "PB"$ $v = 99$

# Another Example

This use of the method avoids creating an alias: it **swaps** `v` with the value in `m` that was previously associated with `k`.

```
v = m.replaceValue(k, v);
```

## State

```
m = { ("PB", 99),  
      ("BW", 17) }  
k = "PB"  
v = 85
```

```
m = { ("PB", 85),  
      ("BW", 17) }  
k = "PB"  
v = 99
```

# key

K key(V value)

- Reports some key associated with `value` in **this**.
- Aliases: reference returned by `key`
- Requires:  
*value is in RANGE(this)*
- Ensures:  
*(key, value) is in this*

# Example

<b>Code</b>	<b>State</b>
	<pre>m = { ("PB", 99),       ("BW", 17) } k = "xyz" v = 99</pre>
<pre>k = m.key(v);</pre>	

# Example

<b>Code</b>	<b>State</b>
	<pre>m = { ("PB", 99),       ("BW", 17) } k = "xyz" v = 99</pre>
<pre>k = m.key(v);</pre>	
	<pre>m = { ("PB", 99),       ("BW", 17) } k = "PB" v = 99</pre>

## Code

```
k = m.key(v);
```

The method `value` is part of the *intended* use of a `Map` and is efficient in most classes that implement `Map`; the method `key` is rarely of interest and is inefficient in most classes that implement `Map`.

```
m = { ("PB", 99),  
      ("BW", 17) }  
k = "PB"  
v = 99
```

# hasValue

**boolean** hasValue(V value)

- Reports whether there is a pair in **this** whose second component is `value`.
- Ensures:

*hasValue* =

*(value **is in** RANGE(**this**))*

# Example

<b>Code</b>	<b>State</b>
	<pre>m = { ("PB", 99),       ("BW", 17) } v = 17</pre>
<pre>boolean b =     m.hasValue(v);</pre>	

# Example

<b>Code</b>	<b>State</b>
	$m = \{ ("PB", 99), ("BW", 17) \}$ $v = 17$
<b>boolean</b> b = m.hasValue(v);	
	$m = \{ ("PB", 99), ("BW", 17) \}$ $v = 17$ $b = \mathbf{true}$

**Code**

```
boolean b =  
    m.hasValue(v);
```

The method `hasKey` is part of the *intended* use of a `Map` and is efficient in most classes that implement `Map`; the method `hasValue` is rarely of interest and is inefficient in most classes that implement `Map`.

```
m = { ("PB", 99),  
      ("BW", 17) }  
v = 17  
b = true
```

# combineWith

**void** combineWith (Map<K, V> m)

- Combines `m` with **this**.
- Updates: **this**
- Clears: `m`
- Requires:

*DOMAIN*(**this**) *intersection*

*DOMAIN*(`m`) = { }

- Ensures:

**this** = #**this** union #`m`

# Example

<b>Code</b>	<b>State</b>
	<pre>m1 = { ("PB", 99),         ("BW", 17) } m2 = { ("PS", 99) }</pre>
<pre>m1.combineWith(m2);</pre>	

# Example

<b>Code</b>	<b>State</b>
	$m1 = \{ ("PB", 99), ("BW", 17) \}$ $m2 = \{ ("PS", 99) \}$
<code>m1.combineWith(m2);</code>	
	$m1 = \{ ("PB", 99), ("BW", 17), ("PS", 99) \}$ $m2 = \{ \}$

# sharesKeyWith

**boolean** sharesKeyWith (Map<K, V>  
m)

- Reports whether **this** and **m** have any keys in common.
- Ensures:

*sharesKeyWith =*

*(DOMAIN (**this**) **intersection***

*DOMAIN (m) **/=** { })*

# Example

<b>Code</b>	<b>State</b>
	$m1 = \{ ("PB", 99), ("BW", 17) \}$ $m2 = \{ ("PS", 99) \}$
<b>boolean</b> b = m1.sharesKeyWith(m2);	

# Example

<b>Code</b>	<b>State</b>
	<pre>m1 = { ("PB", 99),         ("BW", 17) } m2 = { ("PS", 99) }</pre>
<pre>boolean b =   m1.sharesKeyWith(m2);</pre>	
	<pre>m1 = { ("PB", 99),         ("BW", 17) } m2 = { ("PS", 99) } b = <b>false</b></pre>

# iterator

`Iterator<Map.Pair<K, V>> iterator()`

- Returns an iterator over a set of elements of type `Map.Pair<K, V>`.

- Ensures:

*`entries (~this.seen * ~this.unseen) = this`*  
*and*

*`| ~this.seen * ~this.unseen | = | this |`*

# Example

- Suppose you have a `Map` that keeps track of the names and associated salaries of all employees in the company:

```
Map<String, NaturalNumber> m =  
    new Map1L<> ();
```

...

# Sample For-Each Loop: Danger!

- Here's how you *might try* to give every employee a \$10,000 raise:

```
NaturalNumber raise =  
    new NaturalNumber2(10000);  
for (Map.Pair<String, NaturalNumber> p : m) {  
    NaturalNumber salary = p.value();  
    salary.add(raise);  
}
```

# Sample For-Each Loop:

Draw this diagram: `p` holds aliases to some key and its associated value in `m`; the method `value` returns an alias to a `NaturalNumber` that is also in the `Map m`; so, changing that `NaturalNumber` incidentally changes the values of *both* `p` and `m` (even though no `Map` method is called in the loop).

```
Na
new NaturalNumber(1000);
for (Map.Pair<String, NaturalNumber> p : m) {
    NaturalNumber salary = p.value();
    salary.add(raise);
}
```

# Sample For-Each Loop: Danger!

- Here's how you *might try* to give every employee a \$10,000 raise:

```
NaturalNumber raise =  
    new NaturalNumber2(10000);  
for (Map.Pair<String, NaturalNumber> p in m) {  
    NaturalNumber salary = p.value();  
    salary.add(raise);  
}
```

***Danger!***

This violates the rules for using  
iterators and for-each loops!

# The Safe Way

- Here's how you *should* give every employee a \$10,000 raise:

```
NaturalNumber raise = new NaturalNumber2(10000);
Map<String, NaturalNumber> temp = m.newInstance();
temp.transferFrom(m);
while (temp.size() > 0) {
    Map.Pair<String, NaturalNumber> p =
        temp.removeAny();
    p.value().add(raise);
    m.add(p.key(), p.value());
}
```

Draw this diagram: `p` holds references to some key and its associated value, but now they are *not* in any `Map` and `p` is *not* in any `Map`; the method `value` returns an alias to a `NaturalNumber` in the `Map.Pair p`; so, changing that `NaturalNumber` does *not* incidentally change the value of `m` or `temp` (even though that actually would be OK for this loop).

```
temp.transferFrom(m);  
while (temp.size() > 0) {  
    Map.Pair<String, NaturalNumber> p =  
        temp.removeAny();  
    p.value().add(raise);  
    m.add(p.key(), p.value());  
}
```
