# JavaScript: Coercion and Functions

Computer Science and Engineering ■ College of Engineering ■ The Ohio State University

Lecture 23

### Conversion of Primitive Values

		string	number	boolean
numbers	0	"0"		false
	-0	"0"		false
	1	"1"		true
	NaN	"NaN"		false
	Infinity	"Infinity"		true
	-Infinity	"-Infinity"		true
	6.022e23	"6.022e+24"		true

### Conversion of Primitive Values

		string	number	boolean
boolean	true	"true"	1	
	false	"false"	0	
strings	11 11		0	false
	11 11		0	true
	"1.2"		1.2	true
	"0"		0	true
	"one"		NaN	true

### Conversion of Primitive Values

		string	number	boolean
undefined	undefined	"undefined"	NaN	false
null	null	"null"	0	false

## Summary of (Simple?) Rules

- How do numbers convert to things?
  - Boolean: 0 is false, non-0 is true (exception: NaN)
- How do strings convert to things?
  - Numbers: non-valid syntax give NaN (exception: empty/blank give 0)
  - Boolean: true, only empty string is false
- □ How does undefined convert to things?
  - Number: NaN
- How does null convert to things?
  - Number: 0

### Easier? Column-Major View

```
Computer Science and Engineering ■ The Ohio State University
```

- How do things convert to boolean?
  - Empty string is false
  - Numbers (+/-)0 and NaN are false
  - undefined and null are false
- □ Aka "falsy" (vs. "truthy")
- □ Importance: Boolean contexts
  if (pet)... // evaluate pet as a boolean
- □ Pitfall: &&, || may not result in a boolean
  - x || y means x ? x : y (first x converted)
  - Old idiom: !!x forces conversion to boolean

### Easier? Column-Major View

- Computer Science and Engineering The Ohio State University
- □ How do things convert to Numbers?
  - Empty (and whitespace) string is 0
  - Non-numeric strings are NaN
  - undefined is NaN
  - null is 0
- □ Importance: Used in == evaluation

#### == Evaluation is... Different

- When types do not match, coerce:
  - null & undefined (only) equal each other
  - Strings & booleans converted to numbers

- Pitfall: NaN is not equal to NaN
- When *one* operand is an object:
  - Convert via valueOf (fall back toString)
  - Result then compared with usual == rules
  - Note: no coercion when both operands are references (== means reference equality)
- □ Sanity:
  - Use === since it never coerces

### Your Turn

#### Evaluate: True or false?

```
true == '1'
```

### Surprising Consequences

```
false == 'false'
                     //=>
false == '0'
                      //=>
                      //=>
!!'0'
('0' == 0) && (0 == '') &&
               ('0' != '') //=>
(NaN == true) || (NaN == false)
                      //=>
                      //=>
!!NaN
(NaN != 0) \&\& (!!NaN == !!0)
                      //=>
```

dorey.github.io/JavaScript-Equality-Table

Named functions: declaration & use function foo(a, b) { ... } foo("hi", 3); Anonymous functions function(a, b) { ... } // how is such a thing invoked? Functions are objects (first-class citizens) They can be assigned to variables! let foo = function(a, b) {...}; foo("hi", 3); let bar = foo; // cf. let bar = foo(); bar("world", 17);

```
Circle
centerX
centerY
                              this.centerX =
                              this.centerY = y;
 radius
  area
                            return Math.PI
                                               this.radius *
                                               "this.radius
```

## Functions Can Be Arguments

```
function apply (f, a) {
  return f(a); // f is a function!
function square(i) {
  return i * i;
```

```
apply(square, 5) //=> 25
```

#### Functions Can Be Return Values

```
function grantDegree() {
  function addTitle(name) {
    return `Dr. ${name}`;
  return addTitle; // a function!
let phd = grantDegree();
phd("Turing"); // phd is a function
phd(3/2);
         //=> "Dr. 1.5"
```

```
function greaterThan(bound) {
  function compare(value) {
    return value > bound;
  return compare; // 1-arg function
let testPos = greaterThan(0);
testPos(4) //=> true
testPos(-3) //=> false
```

## Closures + Anonymity

```
function greaterThan(bound) {
  function compare(value) {
    return value > bound;
  return compare; // 1-arg function
let testPos = greaterThan(0);
testPos(4) //=> true
testPos(-3) //=> false
```

```
Computer Science and Engineering ■ The Ohio State University
```

```
function greaterThan(bound) {
  let compare = function(value) {
    return value > bound;
  return compare; // 1-arg function
let testPos = greaterThan(0);
testPos(4) //=> true
testPos(-3) //=> false
```

```
Computer Science and Engineering ■ The Ohio State University
```

```
return function(value) {
    return value > bound;
let testPos = greaterThan(0);
testPos(4) //=> true
testPos(-3) //=> false
```

function greaterThan(bound) {

- Concise notation for anon. functions
- □ Syntax:
  - Omit function keyword
  - Place arrow => between params and body
  - (a, b = 10) => { ... }
    (r) => { return Math.PI \* r\*\*2 }
- For one-liner, can omit return and {} 's
   (r) => Math.PI \* r\*\*2
- For one parameter, can omit () 's
  r => Math.PI \* r\*\*2
- Use where function expressions needed
  let area = r => Math.PI \* r\*\*2

### Closures + Anonymity Revisited

```
function greaterThan(bound) {
   return value => value > bound;
}
```

```
let testPos = greaterThan(0);
testPos(4) //=> true
testPos(-3) //=> false
```

## Summary

- □ Truthy, falsey, and friends
  - Type coercion is everywhere
  - Coerce to boolean in conditionals
  - Coerce to number for ==
- Functions as first-class citizens
  - Can be passed as arguments
  - Can be returned as return values!
  - Closure: carry their context

- Immediately Invoked Function Expression
  - Define and invoke function at the same time
- Basic forms:
  - (function() { /\* code here \*/ })();
  - let n = function() { /\* code here\*/ }();
- Work-around for weird JavaScript scoping
  - var scopes variables to the enclosing function
  - IIFE creates a lexical scope (with closures)
- Modern JavaScript has let (and const)
  - These scope variables to the enclosing block
  - General advice: prefer let to var
  - But IIFEs are still encountered in the wild
