CSE 6341, Programming Project 3
Due Monday, October 23, 11:59 pm (30 points)

The goal of this project is to build an interpreter for the language from Project 2 (with some minor changes to the language, as defined below). The semantics to be implemented was discussed when we considered the definition of operational semantics. Your implementation will use the code for AST building from Project 2, with minor changes to Interpreter.java. Assume that the input program successfully passes the typechecking defined in Project 2; you do not need to perform this typechecking in your implementation of Project 3.

Set up
cd /home/buckeye.8/6341/proj; mkdir p3; cd p3
wget web.cse.ohio-state.edu/~rountev.1/6341/project/p2.tar.gz
tar -xvzf p2.tar.gz --strip-components=1
make
./plan t1
Edit Interpreter.java to add the following new exit codes:
public static final int EXIT_UNINITIALIZED_VAR_ERROR = 3;
public static final int EXIT_DIV_BY_ZERO_ERROR = 4;
public static final int EXIT_FAILED_STDIN_READ = 5;

Restriction
To simplify the project, the following restriction will be imposed on all input programs: no two variables have the same name. This also applies to variables that are in different blocks: so, code such as
```
int z = ...; { ... { int z = ...; } }
```
is never going to be part of a valid input program.

You do not have to check whether this restriction is satisfied by the input program: just assume that it is and implement your interpreter under this assumption.

Details
The semantics was described in class. A few additional details:

1) Do not print the program. Do not print the state. Only print (1) expression values at print statements, and (2) error messages for run-time errors.

2) You must catch run-time errors for “use of uninitialized variable” and “division by zero” and then exit the interpreter with the corresponding error codes listed above.

3) readint and readfloat expressions should read from UNIX stdin and produce a value of the corresponding type. If this reading cannot be performed successfully, the interpreter should exit with error code EXIT_FAILED_STDIN_READ. A simple way to implement this functionality is to use a Scanner object from java.util: e.g., at the very beginning of program execution create an object Scanner s = new Scanner(System.in) and then call s.nextLong() and s.nextDouble() whenever you need to evaluate a readint or readfloat expression. When executing the interpreter from the command line, you can put the input data in some file data_file and then do ./plan code_file < data_file
4) Type INT in our language should be implemented by a Java `long` type; type FLOAT in our language should be implemented by a Java `double` type.

5) Since each variable declaration uses a unique name (due to the restriction described above), you can implement the state $\sigma$ with one map from variable names to values. There is no need to use a tree of maps. At the beginning of execution, the map is empty.

6) The evaluation of boolean `&&` and `||` operators should use short-circuit semantics.

7) A natural implementation approach is to add to each expression class a method `evaluate` that takes as input a reference to the state, evaluates the expression, and returns the resulting value. Similarly, for each statement class you can use a method `execute` that takes as input a reference to the state, executes the statement, and as a result changes the state.

Testing
Write many test cases and test your interpreter with them. Submit at least 5 test cases with your submission. The test cases you submit will not affect your score for the project. Put them in the same location as the provided file t1 and name them t2, ...

Submission
After completing your project, do
```
cd p3; make clean; cd ..
tar -cvzf p3.tar.gz p3
```
Then submit `p3.tar.gz` in Carmen.

General rules (copied from the course syllabus)

1) Your submissions must be submitted electronically via Carmen by midnight on the due date. The projects must compile and run on `stdlinux`. Some students prefer to implement the projects on a different machine, and then port them to `stdlinux`. If you decide to use a different machine, it is entirely your responsibility to make the code compile and run correctly on `stdlinux` before the deadline. In the past many students have tried to port to `stdlinux` too close to the deadline, leading to last-minute problems and missed deadlines.

2) Projects should be done independently. General high-level discussion of projects with other students in the class is allowed, but you must do all design, programming, testing, and debugging independently. Projects that show excessive similarities will be taken as evidence of cheating and dealt with accordingly. Code plagiarism tools may be used to detect cheating. See more details in the Syllabus under “Academic integrity”.

3) The projects are due by 11:59 pm on the due day. No exceptions will be made to this deadline: if you submit at 12:00 am, your submission will be late. Please plan your time carefully and do not submit in the last minute. You can submit up to 24 hours after the deadline; if you do so, your project score will be reduced by 10%. If you submit more than 24 hours after the deadline, the submission will not be accepted, and you will receive zero points for this project.

4) Accommodations for sickness and other special circumstances will be made based on university guidelines. Please contact me ahead of time to arrange for such accommodations.
