Model-View-Controller (MVC) Design Pattern

Lecture 25

Motivation

- Basic parts of any application:
  - Data being manipulated
  - A user-interface through which this manipulation occurs
- The data is logically independent from how it is displayed to the user
  - Display should be separately designable/evolvable
- Example: grade distribution in class
  - Displayed as both pie chart and/or bar chart
- Anti-example: see BigBlob
  - Presentation, logic, and state all mixed together
Model-View-Controller Pattern

- **Model**
  - The data (ie state)
  - Methods for accessing and modifying state

- **View**
  - Renders contents of model for user
  - When model changes, view must be updated

- **Controller**
  - Translates user actions (ie interactions with view) into operations on the model
  - Example user actions: button clicks, menu selections

Basic Interactions in MVC

```
Input
"user action"

Controller
"change data"

Model

Output
"change display"

View
```

Example user actions: button clicks, menu selections
Implementing Basic MVC in Swing

- Mapping of classes to MVC parts
  - View is a Swing widget (e.g., JFrame, JButton, etc.)
  - Controller is an event listener (e.g., ActionListener)
  - Model is an ordinary Java class (or database)

- Alternative mapping
  - View is a Swing widget and includes (inner) event listener(s) as event handlers
  - Controller is an ordinary Java class with “business logic”, invoked by event handlers in view
  - Model is an ordinary Java class (or database)

- Difference: Where is the event listener?
  - Regardless, model and view are completely decoupled (linked only by controller)

Mechanics of Basic MVC

- Setup
  - Instantiate model
  - Instantiate view
    - Has reference to a controller, initially null
  - Instantiate controller with references to both
    - Controller registers with view, so view now has a (non-null) reference to controller

- Execution
  - View recognizes event
  - View calls appropriate method on controller
  - Controller accesses model, possibly updating it
  - If model has been changed, view is updated (via the controller)

- Example: CalcMVC
  - CalcModel, CalcView, CalcController
Extended Interactions in MVC

Role of Extended Pattern

- **Background**: Observer pattern
  - One object is notified of changes in another
  - In extended MVC, view is an observer of model

- **Application within MVC**
  - Asynchronous model updates
    - Model changes independent of user actions
    - Associated view must be notified of change in order to know that it must update
  - A model may have multiple views
    - But a view has one model
    - All views have to be updated when model changes
Mechanics of Extended MVC

- Setup
  - Instantiate model
    - Has reference to view, initially null
  - Instantiate view with reference to model
    - View registers with model
  - Instantiate controller with references to both
    - Controller registers with view

- Execution
  - View recognizes event
  - View calls appropriate method on controller
  - Controller accesses model, possibly updating it
  - If model has been changed, it notifies all registered views
  - Views then query model for the nature of the change, rendering new information as appropriate

Problems with Classic MVC

- Controller might need to produce its own output
  - eg Popup menu

- Some state is shared between controller and view, but does not belong in model
  - eg Selection (highlighted text)

- Direct manipulation means that user can interact (control) visual elements (views)
  - eg Scrollbar

- Overall issue: Input and output are often intermingled in a GUI
  - Result: View and controller are tightly coupled
Delegate-Model Pattern

- Model
  - Data, same as before
- Delegate
  - Responsible for both input and output
  - A combination of both view and controller
- Many other names
  - UI-Model
  - Document-View

Basic Interactions in Delegate Model

- Input
  - "user action"
- Output
  - "change display"
  - "change data"
Basic Interactions in Delegate Model

Mechanics of Delegate Model

- **Setup**
  - Instantiate model
    - As with MVC, model does not know/care about UI
  - Instantiate delegate with reference to model

- **Execution**
  - Delegate recognizes event and executes appropriate handler for the event
  - Delegate accesses model, possibly updating it
  - If model has been changed, UI is updated

- **Example: CalcV3**
  - CalcModel, CalcViewController
  - Note: CalcModel is exactly the same as with CalcMVC
Notes

- Litmus test: Swapping out user interface
  - Can the model be used, without modification, by a completely different UI?
  - eg Swing vs console text interface
- Model can be easily tested with JUnit
- Model actions should be quick
  - GUI is frozen while model executes
  - Alternative: multithreading, which gets much more complicated

Supplemental Reading

- Oracle Technology Network
  - “Java SE Application Design with MVC”
    - [http://www.oracle.com/technetwork/articles/javase/index-142890.html](http://www.oracle.com/technetwork/articles/javase/index-142890.html)
- OnJava article
  - “A Generic MVC Model in Java”
Summary

- Motivation: Information hiding
  - Data (state) vs user interface
  - State should be agnostic of user interface

- Model-View-Controller
  - Model contains state (data)
  - View displays model to user (presentation)
  - Controller modifies model (business logic)

- UI-Model
  - Allows for tight coupling between view and controller
  - Preserves most significant separation
